

Management System for a Coffee Shop

1. Problem Description

A small coffee shop faces various operational problems due to a lack of organization in its internal processes. One of the main issues is inventory control, as there is no accurate record of ingredients such as coffee, milk, bread, and other supplies. This leads to shortages during peak hours or unnecessary waste due to over-purchasing.

Sales tracking is also inefficient, as many transactions are recorded manually or without a formal system, resulting in accounting errors and difficulty in tracking income. Similarly, customer orders are not always properly managed, especially during busy hours, which can cause confusion, delays, or incorrect deliveries.

Another important issue is the lack of customer tracking, which prevents the business from offering personalized service or special promotions. In addition, product preparation is not planned based on real demand, leading to imbalance between production and consumption.

There is also poor employee management, as there is no clear control of schedules, shifts, or assigned tasks. Finally, the absence of reports and organized records limits business analysis and makes decision-making more difficult.

2. General Description

Small coffee shops often operate using manual processes that may work at the beginning but become problematic as customer demand increases. The lack of control in areas such as inventory, sales, customer service, and production directly affects business efficiency.

In many cases, information is not recorded in a structured way, which leads to order mistakes, financial losses, and overall disorganization. Additionally, the lack of customer and product tracking reduces the ability to improve service and adapt to market needs.

This situation also impacts customer experience, as service times may be longer and orders less accurate. Overall, these factors reduce productivity and limit business growth.

3. Theoretical Background

Coffee shops are businesses dedicated to preparing and selling coffee-based beverages, along with complementary products such as desserts, sandwiches, and snacks. Their operation depends on proper coordination between product preparation, customer service, and inventory management.

Inventory control is essential in this type of business because ingredients are often perishable and require careful management to avoid waste. Likewise, sales records help evaluate financial performance and support daily operational decisions.

Customer management is also important, as it allows businesses to identify frequent customers and improve service quality through personalized attention. On the other hand, production planning helps maintain a balance between supply and demand, especially during peak hours.

In general, proper organization of internal processes improves operational efficiency, reduces losses, and enhances customer service quality.

4. Main Concept

The main concept identified is the lack of control and organization in the internal processes of the coffee shop, which directly affects its overall operation.

This problem is reflected in inefficient inventory management, poor sales tracking, weak order handling, and the absence of customer follow-up. Additionally, disorganization in production and employee management reduces overall business efficiency.

Therefore, it is necessary to implement mechanisms that allow proper recording, organization, and control of information in order to improve daily operations, optimize resources, and provide a better customer experience.
